

Databases Narrative

This artifact is a full-stack web application that is a travel vacation website. The original artifact started development last semester and was finished at the beginning of March. I included this artifact because I think it demonstrates a wide variety of skills ranging from frontend to backend development, API endpoints, HTTP methods, and databases. Specifically, the admin single page application, the frontend website, and the MongoDB database showcase the most skills and abilities. Considering the change I had to make around my milestone two enhancement, I could not complete the original enhancement around databases that I had planned. I instead decided to implement database querying on the front-end website. On the travel page, users are now able to search for trips by name, and they can also sort by price low to high, high to low, and they also have a clear button to reset the filters. I did meet the course outcome I planned which was course outcome four. This stated that I would improve the web apps value by showing skills involving database design/implementation, as well as the ability to query and display data from a database on a website. As I enhanced this artifact I learned a great deal around querying data from a database onto a webpage. I had to modify my original data listing to accept queries provided by the user on the front-end web page, which was something I had not messed around with yet. I did run into a challenge when implementing the sorting trips by price, as my cost were of type text in my trip schema. To get around this, I first had to change the type to number, and then I had to go update the actual stored values in the database by logging in through the Admin SPA and reentering the costs. This updated the cost per person values to actual numbers, which in turn allowed my sorting to work successfully.
